

**ENHANCED ABLATION AND MAPPING CATHETER AND
METHOD FOR TREATING ATRIAL FIBRILLATION**

FIELD OF THE INVENTION

The present invention relates to an improved steerable electrode catheter having an irrigated ablation electrode that is particularly useful for treating atrial fibrillation.

BACKGROUND OF THE INVENTION

Atrial fibrillation is a common sustained cardiac arrhythmia and a major cause of stroke. This condition is perpetuated by reentrant wavelets propagating in an abnormal atrial-tissue substrate. Various approaches have been developed to interrupt wavelets, including surgical or catheter-mediated atriotomy. It is believed that to treat atrial fibrillation by radio-frequency ablation using a catheter, continuous linear lesions must be formed to segment the heart tissue. By segmenting the heart tissue, no electrical activity can be transmitted from one segment to another. Preferably, the segments are made too small to be able to sustain the fibrillatory process. A preferred technique for treating atrial fibrillation by radio-frequency ablation would be a "branding iron" approach, where a relatively long electrode can be held stationary in good contact with the heart wall while ablation is completed. In this way, a continuous transmural burn may be effected.

U.S. Patent No. 5,800,428 to Nelson et al. discloses a radio frequency ablation catheter system having a flexible, tubular electrode for creating a continuous linear lesion. The tubular electrode is selectively extendable from the distal end of the catheter. The catheter further comprises mechanisms for remotely manipulating and extending the electrode. However, having an extendable electrode house in the catheter provides less degrees of freedom with respect to the shape, size and length of the tubular electrode. Moreover, the physician has to deal with additional moving and manipulatable parts, adding complexity to the procedure. Further, a retractable electrode can cause contamination because blood or coagulate on the electrode can be pulled into and entrapped inside the catheter. The entrapped coagulate can also affect the ability of the electrode to be further extended and retracted. Accordingly, it would be desirable to provide a catheter design having an electrode for creating linear lesions that overcomes these drawbacks.

U.S. Patent Application No. 10/199,525, entitled "Atrial Ablation Catheter and Method for Treating Atrial Fibrillation" discloses a catheter having an ablation assembly bent relative to

the catheter body and comprising a generally-straight non-retractable tubular electrode formed of a material having shape-memory having at least one irrigation port through which fluid can pass from the inside to the outside of the electrode. However, in order to create lesions that are sufficiently deep to treat arrhythmias, a relatively high level of radio frequency power is often needed, which can result in coagulum formation and tissue charring. The irrigation ports in the tubular electrode described in U.S. Patent Application No. 10/199,525 permit the use of cooling fluid to reduce coagulum formation and tissue charring. However, if the irrigation is not efficiently delivered to the tissue being treated, local hot spots can develop at the tissue/electrode interface. Accordingly, a need exists for an improved catheter containing an elongated electrode that can provide more efficient cooling during ablation.

SUMMARY OF THE INVENTION

The invention is directed to an improved catheter and method for ablating linear lesions while ensuring delivery of cooling saline to the tissue being ablated. In one embodiment, the invention is directed to a catheter comprising an elongated generally-tubular catheter body having proximal and distal ends. An electrode assembly is provided at the distal end of the catheter body. The electrode assembly includes a porous electrode arrangement that is generally transverse to the catheter body. The porous electrode arrangement comprises one or more electrodes electrically connected to a suitable energy source and a porous sleeve mounted in surrounding relation to the one or more electrodes and defining an open space between the porous sleeve and the one more electrodes. One or more irrigation openings fluidly connect the open space to a lumen extending through the catheter through which fluid can pass. In use, fluid passes through the lumen in the catheter, through the one or more irrigation openings, into the open space and through the porous sleeve.

In another embodiment, the invention is directed to a catheter comprising an elongated generally-tubular catheter body having proximal and distal ends. An electrode assembly is provided at the distal end of the catheter body. The electrode assembly comprises a non-conductive tubing mounted on the distal end of the catheter body and having a lumen extending therethrough. A generally-straight porous electrode is mounted on the non-conductive tubing and is generally transverse to the axis of the catheter body. The porous electrode comprises one or more electrodes electrically connected to a suitable energy source and a porous sleeve mounted in surrounding relation to the one or more electrodes and defining an open space between the

porous sleeve and the one more electrodes. One or more irrigation openings fluidly connect the open space to the lumen extending through the non-conductive tubing.

5 The invention is also directed to a method for ablating heart tissue. The method comprises inserting the distal end of a catheter as described above into the heart of a patient and forming at least one linear lesion in the atrial tissue with the porous electrode by simultaneously supplying ablation energy to the one or more electrodes and introducing fluid through the irrigation openings so that the fluid passes through the porous sleeve.

10 In another embodiment, the invention is directed to a method for treating atrial fibrillation. The method comprises inserting the distal end of a catheter as described above into an atrium of the heart of a patient and forming at least one linear lesion in the atrial tissue with the porous electrode by simultaneously supplying ablation energy to the one or more electrodes and introducing fluid through the irrigation openings so that the fluid passes through the porous sleeve.

DESCRIPTION OF THE DRAWINGS

These and other features and advantages of the present invention will be better understood by reference to the following detailed description when considered in conjunction with the accompanying drawings wherein:

FIG. 1 is a side cross-sectional view of an embodiment of the catheter of the invention.

FIG. 2 is a side cross-sectional view of a catheter body according to the invention, including the junction between the proximal shaft and distal shaft.

FIG. 3 is a side view of an electrode assembly according to the invention.

FIG. 4 is an end cross-sectional view of the electrode assembly of FIG. 3 along line 4-4.

FIG. 5 is a cross sectional view of a portion of the catheter intermediate section showing one means for attaching the puller wire.

FIG. 6 is a top cross sectional views of a preferred puller wire anchor.

FIG. 7 is a side cross sectional views of the puller wire anchor of FIG. 6.

DETAILED DESCRIPTION

The invention provides a catheter having an irrigated tubular ablation electrode. As shown in FIG 1, the catheter comprises an elongated catheter body **10** having proximal and distal ends with an electrode assembly **15** mounted at the distal end of the catheter body and a control handle **16** at the proximal end of the catheter body.

With reference to FIG. 2, the catheter body **10** comprises an elongated tubular construction having a relatively long proximal shaft **12** and a relatively short distal shaft **14**. The proximal shaft **12** has a single, axial or central lumen **18**. The proximal shaft **12** is flexible, i.e., bendable, but substantially non-compressible along its length. The proximal shaft **12** can be of any suitable construction and made of any suitable material. A presently preferred construction comprises an outer wall **22** made of polyurethane or PEBAX®. The outer wall **22** comprises an imbedded braided mesh of stainless steel or the like to increase torsional stiffness of the proximal shaft **12** so that, when the control handle **16** is rotated, the distal shaft **14** will rotate in a corresponding manner.

The outer diameter of the proximal shaft **12** is not critical, but is preferably no more than about 8 french, more preferably 7 french. Likewise the thickness of the outer wall **22** is not critical, but is thin enough so that the central lumen **18** can accommodate an infusion tube, a puller wire, lead wires, and any other wires, cables or tubes. If desired, the inner surface of the outer wall **22** is lined with a stiffening tube (not shown) to provide improved torsional stability.

In the depicted embodiment, the distal shaft **14** comprises a short section of tubing **19** having three lumens, namely, a lead wire lumen **30**, a puller wire lumen **32**, and an infusion lumen **34**. The wires and tube are described in more detail below. The tubing **19** is made of a suitable non-toxic material that is preferably more flexible than the proximal shaft **12**. A presently preferred material for the tubing **19** is braided polyurethane, i.e., polyurethane with an embedded mesh of braided stainless steel or the like, that is more flexible than the catheter body. The number and size of the lumens is not critical and can vary depending on the various wires, tubes and other components carried by the catheter. In a preferred embodiment, the distal shaft **14** has an outer diameter ranging from about 5 french (.066 inch) to 8 french (.105 inch), and the lead wire lumen **30** and puller wire lumen **32** are generally about the same size, each having a diameter of from about 0.020 inch to about 0.024 inch, preferably 0.022 inch, with the infusion lumen **34** having a slightly larger diameter of from about 0.032 inch to about 0.038 inch, preferably 0.035 inch.

One means for attaching the proximal shaft **12** to the distal shaft **14** is illustrated in FIG. 2. The proximal end of the distal shaft **14** comprises an outer circumferential notch **24** that receives the inner surface of the outer wall **22** of the proximal shaft **12**. The distal shaft **14** and proximal shaft **12** are attached by glue or the like. Other arrangements for joining the proximal and distal shafts are considered within the scope of the invention. For example, the proximal and distal shafts can be made from a single tubing so that the proximal and distal shafts include the

same number of lumens. Alternatively, if a stiffening tube is provided, the stiffening tube can extend slightly beyond the distal end of the proximal shaft **12** (e.g., about 3 mm) and be glued to the proximal shaft, with the proximal end of the distal shaft **14** cored out to receive the distal end of the stiffening tube, creating a lap joint. The lap joint and the butt joint formed between the distal end of the proximal shaft **12** and the proximal end of the distal shaft **14** can be secured with polyurethane glue or the like. In another alternative, the proximal shaft **12** can be thermally fused to the distal shaft **14**.

If desired, a spacer (not shown) can be located within the proximal shaft **12** at its distal end, adjacent the proximal end of the distal shaft **14**. The spacer provides a transition in flexibility at the junction of the proximal shaft and distal shaft, which allows this junction to bend smoothly without folding or kinking. A catheter having such a spacer is described in U.S. Patent No. 5,964,757, the disclosure of which is incorporated herein by reference.

At the distal end of the distal shaft **14** is a non-retractable electrode assembly **15**, as shown in FIGs. 3 and 4. The electrode assembly **15** has proximal and distal ends and comprises an elongated non-conductive tubing **37** mounted on the distal end of the distal shaft **14** and an elongated, porous electrode **38** at the distal end of the non-conductive tubing. In the depicted embodiment, the porous electrode **38** is generally straight and generally transverse to the catheter body **10**, and preferably forms an angle with the axis of the catheter body ranging from about 75° to about 110°.

The proximal end of the non-conductive tubing **37** is generally coaxial with the catheter body **10**, and the mid-section of the non-conductive tubing forms a curve that first bends away from and then back toward and past the axis of the catheter body, with the porous electrode **38** mounted over the straight distal end of the non-conductive tubing, as best shown in FIG. 3. This "foot" or "heel" shape is particularly suitable for ablating a linear lesion with the porous electrode **38** due to its inherent stability. Specifically, it limits the electrode roll when longitudinal push forces are applied to the catheter body, particularly when the porous electrode is placed against the uneven contours of the heart wall. Thus, when the user exerts a longitudinal force on the catheter body, the entire length of the porous electrode tends to exert a force on the tissue rather than the proximal end of the porous electrode being pushed into the tissue and the distal end of the porous electrode being forced away from the tissue.

The generally straight shape of the porous electrode **38** is particularly suitable for creating long linear lesions. However, other shapes for the electrode assembly **15** are also contemplated within the scope of the invention, such as where the porous electrode **38** is curved or bent. A

curved porous electrode **38** could be used for creating curved lesions for pulmonary vein isolation. Other electrode assembly shapes that can be used for the invention are described in U.S. Patent No. 6,371,955, the disclosure of which is incorporated herein by reference.

The non-conductive tubing **37** is generally tubular and includes four lumens, namely, a lead wire lumen **40**, a thermocouple lumen **41**, a stiffening wire lumen **42** and an irrigation lumen **43**. As will become apparent, the number and sizes of the lumens in the non-conductive tubing are not critical and can vary depending on the desired application. The non-conductive tubing **37** can be made of any suitable biocompatible plastic, such as polyurethane or PEBAX®.

The porous electrode **38** comprises one or more electrodes mounted over the non-conductive tubing **37** and covered by a porous material. In the depicted embodiment, a single coiled ribbon electrode **44** is mounted in surrounding relation to the non-conductive tubing **37**. The ribbon electrode **44** can be made of any suitable electrically-conductive metal or other material, such as platinum or gold, and can be an alloy, such as a platinum-iridium alloy. Alternatively, the ribbon electrode **44** can be replaced with a series of ring electrodes or with a thin metal coating that is deposited directly onto the non-conductive tubing **37**. Other electrode arrangements are contemplated within the scope of the invention.

The non-conductive tubing includes a series of irrigation openings **39** in the region of the ribbon electrode **44**. In the depicted embodiment, three irrigation openings **39** are provided between the turns of the ribbon electrode **44**. The irrigation openings **39** fluidly connect the irrigation lumen **43** of the non-conductive tubing **37** to the outside non-conductive tubing. Preferably the irrigation openings **39** are located only on the side of the porous electrode **38** that is to be in contact with the tissue to be ablated, which is typically the side facing away from the catheter body **10**. The irrigation openings **39** can be any suitable shape, such as rectangular or ovular slots or round holes. In an exemplary embodiment, a space of approximately 3.5 mm is provided between the centers of the irrigation openings **39**. As would be recognized by one skilled in the art, the precise number, size, shape and arrangement of irrigation ports **39** can vary as desired.

A porous sleeve **46** is mounted in surrounding relation to the ribbon electrode **44**. The porous sleeve **46** is made of a material through which fluid can pass. The proximal and distal ends of the porous sleeve **46** extend beyond the proximal and distal ends of the ribbon electrode **44**. As discussed further below, the proximal and distal ends of the porous sleeve **46** are sealed over the non-conductive tubing **37** to create an open space **47** between the porous sleeve and the non-conductive tubing and ribbon electrode **44**.

With this design, saline or other fluid can pass out through the irrigation openings 39 between the coils of the ribbon electrode 44 into the open space 47 defined by the porous sleeve 46 and then through the porous sleeve. When radio frequency (RF) energy or other appropriate energy is supplied to the ribbon electrode 44, the RF current is carried to cardiac tissue by saline flow through the porous sleeve 46 while the porous sleeve is in contact with the tissue. The RF current resistively heats the tissue in contact with the porous sleeve 46, causing permanent cellular necrosis of the tissue, thereby creating a linear lesion. The porous sleeve 46 allows for the flow of saline around the ribbon electrode 44 to keep the electrode temperature low during energy application.

This design permits safe delivery of higher levels of RF power that are required to create lesions deep enough to treat arrhythmias such as atrial fibrillation, atrial flutter and ventricular tachycardia. Although with other irrigated electrode designs it is possible for coagulum formation and tissue charring to occur due to inefficient irrigation that results in local hot spots at the tissue/electrode interface, the porous sleeve electrode design ensures that RF current cannot be delivered to the tissue without the presence of the cooling saline or other fluid. Therefore RF lesions can be created only at locations that are also cooled by the saline irrigation.

As noted above, the porous sleeve 46 is made of a material through which saline and other fluid can pass. Preferably the porous sleeve 46 is formed of a generally non-compressible material. As used herein, the term "non-compressible" means that the material generally does not exhibit appreciable or sufficient compressibility between its inner and outer surfaces to conform to surface irregularities of the tissue against which the porous electrode is placed. A particularly suitable material for the porous sleeve 46 is expanded polytetrafluoroethylene (ePTFE), although the sleeve can also be made of other porous materials, such as porous polyethylene, porous silicon, porous urethane, porous nylon, sintered ceramics, and tight weaves of dacron and other woven meshes. Such porous materials are formed using conventional techniques, such as, for example by blowing the material or by drilling micro holes within the material. The porosity of the material desirably ranges between about 5 and 50 microns.

In a particularly preferred embodiment, the porous sleeve 46 comprises ePTFE having an inner diameter of 0.080 inch and an outer diameter of about 0.096 inch, with the ePTFE being expandable to no more than 10% at a distilled water flow rate of 30 to 40 cc/min. The porous electrode preferably has a length L ranging from about 10 to about 25 mm, more preferably from about 10 to about 15 mm, still more preferably about 11 mm. In one embodiment, the degree of porosity of the porous sleeve 46 over its length is generally uniform. This uniformity coupled

with the flow restrictiveness of the material results in the fluid emanating from the porous sleeve 46 in a generally even flow over its entire outer surface.

An infusion tube 48 is provided for infusing fluid, such as saline, to the irrigation openings 39. The infusion tube 48 is preferably made of a biocompatible plastic, such as polyimide. The infusion tube 48 has a distal end anchored in the proximal end of the irrigation lumen 43 of the non-conductive tubing 37. The infusion tube 48 extends through the infusion lumen 34 of the distal shaft 14, through the proximal shaft 12, out the proximal end of the control handle 16, and terminates in a luer hub 49 or the like at a location proximal to the control handle. In an alternative arrangement, a single lumen side arm (not shown) is fluidly connected to the central lumen 18 near the proximal end of the catheter body 10, as described in more detail in U.S. Patent No. 6,120,476, the entire disclosure of which is incorporated herein by reference. Alternatively, the infusion tube 48 can terminate within the distal end of the infusion lumen 34 of the distal shaft 14, with a second infusion tube (not shown) provided that extends from the proximal end of the infusion lumen, through the proximal shaft 12 and out through the control handle 16. Such a design is also described in more detail in U.S. Patent No. 6,120,476.

An electrode lead wire 50 is attached to the ribbon electrode 44 for electrical connection to a suitable connector (not shown), which is attached to a source of ablation energy, such as RF energy (not shown). The electrode lead wire 50 is soldered, welded or otherwise attached to the ribbon electrode 44. The electrode lead wire 50 can comprise any suitable material, and is preferably a copper wire or a Monel wire with an appropriate non-conductive covering over most of its length. The electrode lead wire 50 for the ribbon electrode 38 extends through the lead wire lumen 40 of the non-conductive tubing 37, the lead wire lumen 30 of the distal shaft 14, the central lumen 18 of the proximal shaft 12, and the control handle 16, and is connected to a suitable source of ablation energy (not shown) by means of an appropriate connector as is generally known in the art.

One or more mapping electrodes are mounted over the non-conductive tubing 37. The mapping electrodes enable the user to perform pace mapping to assess tissue contact as well as electrical conductivity within the atrium or other region being treated before and after ablation. In the depicted embodiment two proximal mapping electrodes 52 are mounted proximal to the porous electrode 38, and two distal mapping electrodes 54 are mounted distal to the tubular electrode. Each of the proximal and distal mapping electrodes 52 and 54 comprises a ring electrode that is mounted in surrounding relation to the non-conductive tubing 37, although other electrode arrangements are considered within the scope of the invention. The ring electrodes can

be made of any suitable material, and are preferably made of platinum or an alloy of platinum and iridium. An electrode lead wire **50** is welded, soldered or otherwise attached to each of the mapping electrodes **52** and **54**. Each mapping electrode **52** and **54** preferably has a length ranging from about 0.5 mm to about 2 mm, more preferably from about 0.5 mm to about 1 mm. The spaces between the mapping electrodes **52** and **54**, as well as the spaces between the mapping electrodes and the porous electrode **38**, preferably range from about 0.5 mm to about 3 mm, more preferably from about 0.5 mm to about 1.5 mm.

To maintain the desired shape of the non-conductive tubing **37** and porous electrode **38**, a stiffening wire **56** is provided within the stiffening wire lumen **42** of the non-conductive tubing. The stiffening wire **56** is made of a material having shape-memory, i.e., that can be straightened or bent out of its original shape upon exertion of a force and is capable of substantially returning to its original shape upon removal of the force. A particularly preferred material for the stiffening wire is a nickel/titanium alloy. Such alloys typically comprise about 55% nickel and 45% titanium, but may comprise from about 54% to about 57% nickel with the balance being titanium. A preferred nickel/titanium alloy is nitinol, which has excellent shape memory, together with ductility, strength, corrosion resistance, electrical resistivity and temperature stability. The stiffening wire **56** can have any desired cross-sectional area and need not be circular. The stiffening wire **56** can be pre-shaped to the desired shape using a heat-treating process, as is generally known in the art. Alternatively, the stiffening wire **56** can be eliminated, and the non-conductive tubing can be pre-shaped in the desired configuration.

Additionally, one or more temperature sensing means can be provided for measuring the electrode/tissue interface temperatures near the porous electrode **38** during ablation. Any conventional temperature sensing means, e.g., a thermocouple or thermistor, may be used. In the depicted embodiment, two thermocouples **70** and **72** are provided. Specifically, a distal thermocouple **70** is provided distal to the porous electrode **38**, and a proximal thermocouple **72** is provided proximal to the porous electrode, as described in more detail below. As would be recognized by one skilled in the art, other temperature sensing designs can be used, or the temperature sensors can be eliminated altogether.

To make the electrode assembly **15** described above, an appropriate length of an ePTFE sleeve (for example, around 15 mm) is cut, and five holes are drilled about 1 mm from each end of the ePTFE sleeve evenly about its circumference. A stainless steel mandrel having a Teflon tubing mounted over it is introduced through the ePTFE sleeve. Polyurethane glue is applied to one end of the ePTFE sleeve to form a 1 mm band, and a small rubber O-ring is slid over the

band of polyurethane glue to compress the end of the ePTFE sleeve onto the Teflon over the mandrel. Once the polyurethane glue has cured, the O-ring, Teflon and mandrel are removed. V-shaped notches are cut into each end of the ePTFE sleeve.

The ribbon electrode **44** is formed by wrapping a platinum ribbon around a 0.065 inch gauge pin about 10 times, with no gaps between the turns of the coil. The coil is removed from the pin, and the remaining, uncoiled platinum ribbon is cut off from the coil. Platinum rings are welded to the ends of the wound coil.

The non-conductive tubing **37** is cut to an appropriate length, for example, about 40 mm. The three irrigation openings **39** are drilled into the irrigation lumen **43** of the non-conductive tubing **37** at locations 11 mm, 14.5 mm and 18 mm from what is to be the distal end of the non-conductive tubing. The proximal end of the irrigation lumen **43** is trepanned to expand the lumen so that the infusion tube **48** will fit about 2 mm into the irrigation lumen.

Three electrode lead wires **50**, two for the proximal ring electrodes **52** and one for the ribbon electrode **44**, are introduced into the lead wire lumen **40** of the non-conductive tubing **37**. Five lead wire access holes are punched into the non-conductive tubing **37** using a needle, with two positioned about 7 to 8 mm from the distal end of the non-conductive tubing and three positioned about 20 to 22 mm from the distal end of the non-conductive tubing. The three lead wires **50** are pulled out of the three more proximal holes, and the insulation is removed from the tips of the lead wires. Two of the electrode lead wires **50** are welded to two platinum rings to form the proximal ring electrodes **52**. The third electrode lead wire **50** is welded to what is to be the proximal end of the platinum coil that forms the ribbon electrode **44**. The two platinum rings are then loaded over the non-conductive tubing **37** and aligned with the two most proximal punched holes. The platinum coil is loaded over the non-conductive tubing **37** and aligned with the third most proximal punched hole. The coil is adjusted so that the turns are evenly spaced with the three irrigation openings **39** positioned between the turns, and the platinum coil is anchored in place by applying polyurethane glue to the proximal and distal ends of the ribbon electrode **44**.

Two thermocouple wire holes are punched into the thermocouple lumen **41** of the non-conductive tubing **37** approximately 10 mm and 19 mm from the distal end of the non-conductive tubing, i.e., as positions just proximal and distal to the ribbon electrode **44**. Two thermocouple wire pairs, such as a constantan wire and a copper wire, are introduced into the thermocouple lumen **41** and pulled through the thermocouple wire holes. The insulation is scraped from the distal ends of the thermocouple wires and the two wires of each pair are soldered together at their

distal ends. A short piece of insulating polyimide tubing **74** is inserted over the distal end of each thermocouple wire pair, held in place with polyurethane glue, and cut to a length of about 0.75 mm. The distal ends of the thermocouples **70** and **72** are wrapped around the outside of the non-conductive tubing **37** and glued in place.

The ePTFE sleeve, prepared as described above, is loaded over the platinum coil, which is mounted over the non-conductive tubing **37**. The V-shaped notches in the ePTFE sleeve are aligned with the punched holes for the electrode lead wires **50**. Two additional electrode lead wires **50** are introduced into the lead wire lumen **40** of the non-conductive tubing **37**, pulled out through the two most distal punched holes, and welded to the undersides of two platinum rings to form the two distal mapping electrodes **54**. A 1 mm wide band of polyurethane glue is applied to the non-conductive tubing **37** about 22 mm from its distal end. The ePTFE sleeve is slid under the two proximal mapping electrodes **52** and over the band of glue, with the lead wires being aligned in the V-shaped notch in the proximal end of the ePTFE sleeve. Additional polyurethane glue is applied around the proximal end of the ePTFE sleeve. Another 1 mm wide band of polyurethane glue is applied over the non-conductive tubing about 7 mm from its distal end. Nylon thread is wrapped around the distal end of the ePTFE sleeve to adhere the ePTFE sleeve to the second glue band. The nylon thread is removed, and the two distal mapping electrodes **54** are slid over the distal end of the ePTFE sleeve. Additional polyurethane glue is applied over the distal end of the ePTFE sleeve.

A 0.019 inch pre-shaped Nitinol stiffening wire **56** is introduced into the stiffening wire lumen **42** of the non-conductive tubing **37**, and the Nitinol wire is cut flush with the proximal end of the non-conductive tubing. The infusion tube **48** is loaded into the trepanned (proximal) end of the irrigation lumen **43** of the non-conductive tubing **37**. Polyurethane glue is applied to the proximal end of the non-conductive tubing **37** to seal all lumens except for the irrigation lumen **43**, thereby bonding the infusion tube **47** in place. If desired, a plastic blocker can be inserted into the irrigation lumen **43** during manufacturing to prevent glue from entering into the irrigation lumen.

The distal end of the non-conductive tubing **37** is cut a distance of about 0.5 mm to about 1 mm from the most distal mapping electrode **54**. Polyurethane glue is applied to the distal end of the non-conductive tubing **37**, with some of the glue being allowed to migrate a short distance into the distal end of the lumens in the non-conductive tubing. After curing for about an hour, additional polyurethane glue is added to build up a ball tip **58** at the distal end of the non-conductive tubing **37**, thereby forming an atraumatic tip. As would be recognized by one skilled

in the art, other atraumatic tips could be used, such as those described in U.S. Patent Application No. 09/551,467, entitled "Catheter Having Mapping Assembly," the disclosure of which is incorporated herein by reference.

All of the electrode lead wires **50** and thermocouple wires **70** and **72** extend through the lead wire lumen **30** in the distal shaft **14**. Within the proximal shaft **12**, the wires extend through a protective tubing **36** to keep the wires from contacting other components extending through the central lumen **18**. The protective tubing **36** is preferably anchored at its distal end to the proximal end of the distal shaft **14** by gluing it in the lead wire lumen **30** with polyurethane glue or the like. The electrode lead wires **50** then extend out through the control handle **16** and to a suitable monitoring device or source of ablation energy (not shown), as appropriate, via a suitable connector **60**, as is generally known in the art. The thermocouple wires **70** and **72** similarly extend out through the control handle **16** and to a connector **62** connectable to a temperature monitor (not shown).

A puller wire **84** is provided for deflection of the distal shaft **14**. The puller wire **84** extends through the proximal shaft **12**, is anchored at its proximal end to the control handle **16**, and is anchored at its distal end to the distal shaft **14**. The puller wire **84** is made of any suitable metal, such as stainless steel or Nitinol, and is preferably coated with Teflon® or the like. The coating imparts lubricity to the puller wire **84**.

A compression coil **86** is situated within the proximal shaft **12** in surrounding relation to the puller wire **84**. The compression coil **86** extends from the proximal end of the proximal shaft **12** to the proximal end of the distal shaft **14**. The compression coil **86** is made of any suitable metal, preferably stainless steel. The compression coil **86** is tightly wound on itself to provide flexibility, i.e., bending, but to resist compression. The inner diameter of the compression coil **86** is preferably slightly larger than the diameter of the puller wire **84**. The Teflon® coating on the puller wire **84** allows it to slide freely within the compression coil **86**. If desired, particularly if the lead wires **50** are not enclosed by a protective tubing **36**, the outer surface of the compression coil **86** is covered by a flexible, non-conductive sheath **88**, e.g., made of polyimide tubing, to prevent contact between the compression coil and any other wires within the proximal shaft **12**.

The compression coil **86** is anchored at its proximal end to the outer wall **22** of the proximal shaft **12** by proximal glue joint **90** and at its distal end to the distal shaft **14** by distal glue joint **92**. Both glue joints **90** and **92** preferably comprise polyurethane glue or the like. The glue may be applied by means of a syringe or the like through a hole made between the outer

surface of the proximal shaft **12** and the central lumen **18**. Such a hole may be formed, for example, by a needle or the like that punctures the outer wall **22** of the proximal shaft **12** that is heated sufficiently to form a permanent hole. The glue is then introduced through the hole to the outer surface of the compression coil **86** and wicks around the outer circumference to form a glue joint about the entire circumference of the compression coil **86**.

The puller wire **84** extends into the puller wire lumen **32** of the distal shaft **14**. Preferably the puller wire **84** is anchored at its distal end to the side of the shaft **14**, as shown in FIGs. 5 to 7. A T-shaped anchor **98** is formed which comprises a short piece of tubular stainless steel **100**, e.g., hypodermic stock, which is fitted over the distal end of the puller wire **84** and crimped to fixedly secure it to the puller wire. The distal end of the tubular stainless steel **100** is fixedly attached, e.g., by welding, to a stainless steel cross-piece **102** such as stainless steel ribbon or the like. The cross-piece **102** sits in a notch **104** in a wall of the flexible tubing **19** that extends into the puller wire lumen **32** of the distal shaft **14**. The stainless steel cross-piece **102** is larger than the opening and, therefore, cannot be pulled through the opening. The portion of the notch **104** not filled by the cross-piece **102** is filled with glue **106** or the like, preferably a polyurethane glue, which is harder than the material of the flexible tubing **19**. Rough edges, if any, of the cross-piece **102** are polished to provide a smooth, continuous surface with the outer surface of the flexible tubing **19**. Within the puller wire lumen **32** of the distal shaft **14**, the puller wire **84** extends through a plastic, preferably Teflon®, puller wire sheath **94**, which prevents the puller wire **84** from cutting into the wall of the distal shaft **14** when the distal shaft is deflected. Any other suitable technique for anchoring the puller wire **84** in the distal shaft **14** can also be used.

Longitudinal movement of the puller wire **84** relative to the proximal shaft **12**, which results in deflection of the distal shaft **14**, is accomplished by suitable manipulation of the control handle **16**. Examples of suitable control handles for use in the present invention are disclosed, for example, in U.S. Patent Nos. Re 34,502 and 5,897,529, the entire disclosures of which are incorporated herein by reference.

In use, a suitable guiding sheath is inserted into the patient. An example of a suitable guiding sheath for use in connection with the present invention is the Preface™ Braiding Guiding Sheath, commercially available from Biosense Webster (Diamond Bar, California). The distal end of the sheath is guided into one of the atria. A catheter in accordance with the present invention is fed through the guiding sheath until its distal end extends out of the distal end of the guiding sheath. As the catheter is fed through the guiding sheath, the electrode assembly can be

straightened to fit through the sheath, and it will return to its original shape upon removal of the sheath.

The proximal and/or distal mapping electrodes are then used to measure electrical activity in the region to be ablated. The porous electrode is used to ablate one or more continuous linear lesions by supplying the ribbon electrode with radio frequency energy or other ablation energy and simultaneously introducing fluid through the irrigation openings, into the open space and through the porous sleeve. As used herein, the terminology "linear lesion" refers to any lesion, whether curved or straight, between two anatomical structures in the heart that is sufficient to block a wavelet, i.e., forms a boundary for the wavelet. Anatomical structures, referred to as "atrial trigger spots", are those regions in the heart having limited or no electrical conductivity and are described in Haissaguerre et al., "Spontaneous Initiation of Atrial Fibrillation by Ectopic Beats Originating in the Pulmonary Veins", New England Journal of Medicine, 339:659-666 (Sept. 3, 1998), the disclosure of which is incorporated herein by reference. The linear lesions typically have a length of from about 1 cm to about 6 cm, but can be longer or shorter as necessary for a particular procedure. The thermocouples or other temperature sensing means can be used to monitor the temperature of the tissue during ablation. The mapping, ablation and temperature measuring steps can be performed in any desired order. In one particular embodiment, the porous electrode is used to isolate the pulmonary vein by creating one or more lesions around the pulmonary vein.

In an alternative embodiment, the electrode assembly further includes a location sensor (not shown) for providing location information about the electrode assembly. Such a design is disclosed in U.S. Patent Application No. 10/199,525, entitled "Atrial Ablation Catheter and Method for Treating Atrial Fibrillation," the disclosure of which is incorporated herein by reference. Preferably the location sensor comprises a magnetic-field-responsive coil, as described in U.S. Patent No. 5,391,199, or a plurality of such coils, as described in International Publication WO 96/05758. The plurality of coils enables six-dimensional position and orientation coordinates to be determined. Alternatively, any suitable position sensor known in the art may be used, such as electrical, magnetic or acoustic sensors. Suitable location sensors for use with the present invention are also described, for example, in U.S. Patent Nos. 5,558,091, 5,443,489, 5,480,422, 5,546,951, and 5,568,809, and International Publication Nos. WO 95/02995, WO 97/24983, and WO 98/29033, the disclosures of which are incorporated herein by reference.

If desired, two or more puller wires can be provided to enhance the ability to manipulate the intermediate section. In such an embodiment, a second puller wire and a surrounding second compression coil extend through the proximal shaft and into an additional off-axis lumen in the distal shaft. The first puller wire can be anchored proximal to the anchor location of the second puller wire. Suitable designs of catheters having two or more puller wires, including suitable control handles for such embodiments, are described, for example, in U.S. Patent Nos. 6,123,699, 6,171,277, 6,183,435, 6,183,463, 6,198,974, 6,210,407, and 6,267,746, the disclosures of which are incorporated herein by reference.

The preceding description has been presented with reference to presently preferred embodiments of the invention. Workers skilled in the art and technology to which this invention pertains will appreciate that alterations and changes in the described structure may be practiced without meaningfully departing from the principal, spirit and scope of this invention.

Accordingly, the foregoing description should not be read as pertaining only to the precise structures described and illustrated in the accompanying drawings, but rather should be read consistent with and as support to the following claims which are to have their fullest and fair scope.
